Alerting Abstract WO A

A method for local dynamically connectable digital synchronous multiplex or non-multiplex or asynchronous service networks used as a common service resource (220) for three or more switching units (200;210). A wide area service network has at least one central station (10), and peripheral station(s) (19) within an area/space/region, the common service resource being adaptively shared according to the traffic needs between the switching units.

Information is communicated through the system for each connected digital signal (100) to be communicated through the service network, in such a way that communication of digital signals (100) individually for each time sequence corresponds to a transparent communication, irrespective of each sequence of information of digital signals being communicated through the system or not.

USE/ADVANTAGE - Wide area terrestrial radio system making it possible to use services between several types of standard switching units in a more flexible and cost saving, more efficiently bandwidth saving, less sensitive to interference and not protocol depending method than previously known systems. @ (55pp Dwg.No.10a/27)@

Equivalent Alerting Abstract US A

Each station is connected to one or more switching units. The common service resource is adaptively shared as a function of traffic going to and from the switching units. In one embodiment, capacity in the common service resource is divided into a series of frames. Each frame has a set number of time slices, with information from one or more of the switching units being transferred within a time slice. In one such embodiment, time slices which will not be used during a particular frame due to the lack of or repetitive nature of information from a particular switching unit can be used to transfer information from a different switching unit.

USE/ADVANTAGE - Method for connecting two or more peripheral stations to central station over common service resource.
